## ABSTRACT

**Objectives.** The aim of this case report is to present a single patient case superimposed on the literature knowledge in regard to morphometric mandibular variations observed on dental panoramic radiography and used to identify patients with low bone mass density (BMD).

**Case presentation.** A 62 years old female patient reported to the Blident Help Dental Clinic, for specific visits and treatments, 3 years apart. Based on the digital panoramic radiography and DXA measurement, an osteoporosis evaluation with radiomorphometric indices was performed.

Values for maximum condylar height, maximum coronoid height, projective height of the mandibular ramus, minimum ramus breadth and antegonial angle are higher on both sides. The values decreased for gonial angle, gonial index, mandible cortical width (MCW), superior and inferior mental height and panoramic mandibular indices on both sides. Bigonial distance also decreased and the mandibular cortical index (MCI) changed from C2 category in 2017 to C3 category in 2020.

**Discussions.** This postmenopausal patient had a decline in MCW values which were lower than 3 mm (threshold to differentiate normal) on panoramic radiographs of women with low BMD. Antegonial Index had a decreased value and could be used as a prediction index for osteoporosis. MCI index changed from C2 to C3 in correlation with the changes of bone mass density in lumbar spine.

**Conclusions.** MCI, MCW, antegonial index and bone density played an important role in determining significance of effects of lower BMD at postmenopausal on the mandibular ramus region.

**Keywords:** postmenopause, radiomorphometric indices, osteoporosis

## INTRODUCTION

Osteoporosis is a systemic disease that is considered a public health problem due to its social impact. The disease is altering the bone structure and causes a decrease in bone mineral density (BMD), which increases bone fragility and susceptibility to fractures. Although dual X-ray absorptiometry (DXA) is considered the gold standard for the assessment of BMD, analysis of multiple radiomorphometric indices has been performed to identify low BMD predictors. BMD predictors may play an important role in examinations by dentists

to properly monitor bone density measurements for low BMD and osteoporosis assessments.

There is a wealth of research in the field of dentistry investigating whether panoramic radiography can be applied to identify patients at risk for reduced bone mass and osteoporosis. This would allow dentists to make aware patients of the possible underlying treatment and to present this risk before the patient suffers any fracture.

The mandible, like other bones, is one of the bones in the body that is affected by aging and changes in metabolic function and hormonal disorder.

ders. To forensic medicine, the mandible is considered a good indicator for distinguishing changes in tooth or bone morphology and sexuality by gender and age (gonial angle, mandibular index, panoramic index) of bones affected with osteoporosis (especially postmenopausal women). The height and depth of the ramus may vary depending on age and as a result of hormonal disturbances and dental status [1].

A commonly used method of subjective analysis is the mandibular cortical index (MCI), introduced by Klemetti for the first time [2]. This index classifies the appearance of the lower mandibular cortex into three categories: C1 – the endosteal margin of the cortex is smooth and sharp on both sides; C2 – endosteal margin shows crescent defects and / or appears to form an endosteal cortical remnant on one or both sides; and the C3 cortical layer forms heavy endosteal cortical residues and is clearly porous specific for patients with osteoporosis [3,4].

The mandible cortical width (MCW) is the thickness of the mandible in the area of the mental foramen, which is a quantitative index. It can also be used to evaluate bone quality [5].

According to Benson et al. [6], mandibular panoramic index (PMI) is the thickness of the lower jaw cortex in the area of mental foramen. It can also be used to evaluate bone quality.

For evaluating the ramus height we evaluated: maximum coronoid height, maximum condylar height, ramus projective height, ramus height and condylar height.

Antegonial index (AI) is the measuring of the cortical width in the region anterior to the gonion at a point identified by extending a “best fit” line on the anterior border from the ascending ramus down to the lower border of the mandible [7].

The gonial index is the thickness of the lower jaw cortical, measured at half the angle between the lines tangent to the posterior edge of the branch and to the lower part of the lower jaw, which has a normal value higher than 1.2 [8].

Gonial angle (GA): was assessed by drawing a line tangent to the lower edge of the mandible and another line tangent to the posterior edge of the ascending frame of the mandible, proposed by Mattila et al. [9]. The intersection of these lines forms the gonial angle .

Antegonial angle (AA) is formed by two lines drawn parallel to the opposite area which intersected the deepest point of the antegonial notch [9].

## AIM

The aim of this case report is to present a single patient case superimposed on the literature knowledge in regard to morphometric mandibular variations observed on dental panoramic radiography and used to identify patients with low BMD.

The informed consent was obtained prior to the start of the study. All records, documents, X-rays and case report forms were confidential. Personal data, such as a person's name or any identifiable data, is not retrieved to protect the confidentiality of the data. Only the chief investigator and the investigating money had access to the records. The study was evaluated by the Board of the Blident Help dental clinic and approved as low level negligible risk human research. The analysis and data processing were completed using SPSS 20.0. The two radiographs were taken with the same panoramic unit Instrumentarium® Model OP 30, Tuusula, Finland considering standard exposure parameters (73Kv, 10mA, 10 sec, total infiltration 2.5mm AL, focal spot 0.3mm and magnification factor 1:1.1). The patient positioning for radiography was made by the same person. The magnification compensation was performed using the magnification factor of 10% provided by the manufacturer (Cliniview 10.0). The measurements for each panoramic radiograph were made by a single investigator. Cliniview 10.0 was used to digitally trace lines on the panoramic radiographs.

## CASE PRESENTATION

A 62 years old female patient reported to the Blident Help Dental Clinic, for specific visits and treatments in October 2017 and in November 2020, 3 years apart. At the second visit the patient reported a 16.66% weight loss in the last year. (from 60 kg to 50 kg). Patient associated affections are osteoporosis and cardiovascular disease under specific treatment. Based on the digital panoramic radiography and DXA measurement, an osteoporosis evaluation with radiomorphometric indices was performed in an effort to increase the dentist's role for detecting the potential osteoporosis patients.

We observed a decrease of body mass index from 21.09 to 18.18 after these 3 years, including the patient from normoponderal to subponderal category. From Bone Mineral density measurements, T score for lumbar spine (L1-L4) decreased from -2.1 (in 2017) to -3.1 (2020) and T score for left femur decreased from -0.8 to -1.1.

After morphometric measurements on the panoramic radiography we observed that the values for maximum condylar height, maximum coronoid height, projective height of the mandibular ramus, minimum ramus breadth and antegonial angle are higher on both sides. The values decreased for gonial angle, gonial index, MCW, superior and inferior mental height and panoramic mandibular indices on both sides. Bigonial distance decreased from 153.4 (in 2017) [figure 1] to 150.3 (in 2020) [figure 2]. Mandibular cortical index also changed from C2 category in 2017 to C3 category in 2020.

FIGURE 1. Patient panoramic radiography from 2017

FIGURE 2. Patient panoramic radiography from 2020

There is an opposite trend of evolution between right and left part of the condylar height, ramus height and antegonial index: on one part the values are increasing and on the other part are decreasing [table 1].

## DISCUSSIONS

Osteoporosis is a disease that causes loss of bone mass or strength results in fractures due to

TABLE 1. Values of the radiomorphometric indices in 2017 compared to 2020

	2017	2020	2017	2020
	right side	right side	left side	left side
Maximum condylar height	56.5	59.1	57	59
Maximum coronoid height	58.8	59.6	54.3	56.6
Projective height	49.7	54.5	53.3	55.2
Maximum ramus breadth	36.8	36.9	37	36.4
Minimum ramus breadth	26.8	26.4	27.8	25.2
Condylar height	9.3	9.7	9	9
Ramus height	36.3	37	36.8	36.5
Gonial angle	127.1	126.5	128.5	127.1
Gonial index	1.2	1.1	1.2	1
Antegonial angle	187	192.9	188.8	194.4
Antegonial index	2.4	2.4	2.7	2.1
Superior mental height	15.4	14.7	15.5	15
Inferior mental height	12.5	11.9	12.8	12
MCW	3.2	3	3	2.9
PMI	0.229	0.226	0.226	0.215
PMI superior	0.208	0.204	0.206	0.193
PMI inferior	0.256	0.252	0.25	0.242

fragility. Therefore, the characteristic feature of this bone disease is the gradual reduction of bone density, which makes the patient more susceptible to fractures. The most common fractures are at the spine level and long bones [10]. Hormonal disorders, osteoporosis, osteopenia, recurrent pregnancy and lactation all affect bone shape and thickness [11,12]. Comparing women under 50 years of age for ramus height and bone density, Larhen et al. and Ali et al. [13,14] showed that female postmenopausal decline had an effect on the mandible in this area.

Bhatnagar et al. [15] also showed a significant link between the level of erosion at the mandibular cortex and bone mass density. Panoramic radiography has 96% efficiency and 60% sensitivity in the assessment of osteoporosis, indicating that it is an effective control tool for osteoporosis.

In this study the patient MCI index changed from C2 to C3 with a decreasing of the T score at the lumbar spine. Mansour et al. [16] found a significant association between MCI and bone mass density in lumbar spine. Patients classified as C3 in the MCI had the lowest BMD, followed by C2 and C1.

Kim et al. [17] found that the morphological changes in the mandibular cortical bone for the

postmenopausal women were associated with BMD regardless of age, height and weight. Khojastehpour et al. [18] showed a significant relationship between mandibular cortical shape and age. As evidenced by Govindraj and Chandra [19], the risk for patients classified as C2 and C3 increased with age. In our case there were 3 years difference. This may be considered when assessing the postmenopausal women for osteoporosis.

Our patient had a lowering in MCW value from 3.2 to 3 (on the right side) and from 3.2 to 2.9 on the left side. In postmenopausal women there are studies that showed a significant association between thin MCW and low BMD. In these cases the cortical thickness in the osteopenic / osteoporotic group is lower than that of the normal group [18,20,21]. Shakeel et al. [22] showed a positive relationship between MCW and BMD. Ferreira Leite et al. [23] showed that MCW was positively correlated with bone and neck density. These findings correspond with our results.

Our postmenopausal patient had a decline in MCW values, from 3.2 to 2.9. Although the BMD T score for left femur and Spine L1-L4 lowered in these 3 years, the MCW values remained higher than 2.7. This was in agreement with Nagi et al. [24] who found the mandibular cortical to be lower than 3 mm (threshold to differentiate normal) on panoramic radiographs of women with low BMD. For Kim et al. [17] the mean MCW of menopausal women was 2.7 mm, whereas the average MCW value for osteoporosis was 2.22 mm when a woman was diagnosed with osteoporosis. Khojastehpour et al. [18] and Kim et al. [17] showed that age was associated with MCW.

In a recent study, Vijay et al. [25] in addition to MI and MCI assessment, considered indices that are generally not compared such as gonial angle, antegonial angle, antegonial index. Results showed

that Antegonial Index was significantly higher in normal patients ( $> 3.2$ ) compared with people with small bone mass (osteoporosis and osteopenia). Our patient had a decreased value for antegonial index at the first visit (2.4 and 2.7). This could mean that antegonial index could be used as a prediction index for osteoporosis.

Dur-e-Shahwar et al. [26] found no significant change on panoramic radiographs for ramus height and ramus breadth. In contrast, Abu-Taleb et al. [27] found that coronoid ramus height was the only statistically significant predictor of age. In our study, projective mandibular height, maximum condylar height, projective height and minimum cramus breadth increased with age. In contrast, maximum ramus ramus breadth showed inconsistency in variations between left and right measurements.

To our knowledge, we couldn't find studies that have taken into account all the radiomorphometric indices for a comprehensive evaluation. Future research should be conducted to provide a representative sample that accurately reflects the variability of all these indices at the postmenopausal age for osteoporosis.

## CONCLUSIONS

In this study, some effects of postmenopausal age on the ramus region were elucidated, and MCI, MCW, antegonial index and bone density played an important role in determining its significance. It predicts higher risk of osteoporosis and bone loss, especially in postmenopausal women. Thus, as a routine dental examination, dentists could play an important role in diagnosing patients with low BMD and referring them for bone densitometry and osteoporosis investigation.
