ABSTRACT

Objective. To compare the conventional and self-ligating brackets systems from the point of view of the clinician.

Material and methods. A survey was delivered to orthodontists from the international community (n = 130) in order to evaluate and compare different properties of the two systems.

Results. Conventional brackets are preferred when it comes to bonding technique, final results from an aesthetic and functional point of view and quality-price ratio, while self-ligating brackets are elected for improved patient hygiene, less chairside time and reduced friction and global treatment time.

Conclusions. Orthodontists currently use both systems in their practice and each of them has certain features which makes them superior in comparison to the other.

Keywords: orthodontists, perception, conventional brackets, self-ligating brackets

INTRODUCTION

Conventional and self-ligating braces are widely used in the current orthodontics practice. Popularity of the last has grown during the past decade and many of the clinicians use both or have settled for one of the systems [1]. Manufacturers claim several advantages of the self-ligating braces over the conventional ones, the most important trait being the reduced friction between archwires and the bracket slot, thus improving treatment mechanics [2]. Other more effective characteristics include improved patient comfort and oral hygiene, less activation time and reduced global treatment time [3].

The literature provides contradictory information regarding these aspects with research stating that shorter chair time and less incisor proclination are the only significant advantages of self-ligating systems over conventional systems or that time to initial alignment is actually shorter for the conventional brackets than for either the active or passive self-ligating brackets [4,5].

AIM

The purpose of this study is to assess the orthodontist’s point of view on the self-ligating and conventional bracket systems, regarding clinical experience.

MATERIAL AND METHOD

A de novo conceived questionary was elaborated by means of Google Forms and it comprised 23 questions as follows: one single-answer question...
regarding the preference for one of the systems, 20 single-answer questions containing a 1 to 5 scale with the purpose of appreciating different properties and aspects of the bracket systems and two descriptive questions concerning the uses system (Figure 1,2).

The value of Cronbach’s Alpha means that the questions included in the enquiry show proper consistency.

**RESULTS**

**Question 1:** Do you use or have used in your current orthodontic practice?

a. Only the conventional bracket system (MBT, Roth, Alexander etc.)
b. Only the self-ligating bracket system (Damon, H4, PDS etc.)
c. Both systems

**TABLE 3. Answers at the question 1**

<table>
<thead>
<tr>

<th>Frequency</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Both systems</td>
<td>107</td>
<td>82.95%</td>
</tr>
<tr>
<td>Only the conventional bracket system (MBT, Roth, Alexander, etc.)</td>
<td>15</td>
<td>11.63%</td>
</tr>
<tr>
<td>Only the self-ligating bracket system (Damon, H4, PDS, etc.)</td>
<td>7</td>
<td>5.43%</td>
</tr>
<tr>
<td>Total</td>
<td>129</td>
<td>100.00%</td>
</tr>
</tbody>
</table>

As noticed in table 1, 83% of the questioned orthodontist use both system in their praxis.

The following questions have been grouped two by two, alternatively approaching the conventional and the self-ligating systems. Each of them is given a score from 1 to 5 (1 represents the minimum/the worst/the least effective and 5 the maximum/the best/the most effective) for the following physical and chemical proprieties and perceptual/clinical aspects:

- Bonding technique
- Enamel adhesion
- Patient comfort
- Oral hygiene
- Activation time
- Tooth movement – friction
- Global treatment time
- Debonding technique
- Final aesthetic and functional result
- Quality-price ratio

**Questions 2 and 3:** On a scale from 1 to 5, how accessible do you find the bonding technique in the conventional system and the self-ligating system?
Concerning the bonding technique, in the case of the conventional system, the mean of the scores was 4.349±0.8067 (median = 5.000) whilst in the case of the self-ligating system, it was 3.795±1.086 (median = 4.000). The Mann Whitney test, p < 0.0001 (p < 0.05) indicates a statistically significant difference between the medians of the two scores.

Questions 4 and 5: On a scale from 1 to 5, how effective do you find the bracket to enamel adhesion in conventional systems and in self-ligating systems?

Table 7. Answers at the questions 4 and 5

<table>
<thead>

<td>55 (42.64%)</td>
<td>62 (48.82%)</td>
</tr>
<tr>
<td>Total</td>
<td>129</td>
<td>127</td>
</tr>
</tbody>
</table>

Regarding enamel adhesion, in the conventional system, the mean of the scores was 4.264±0.7450 (median = 4.000) while in the self-ligating system, the mean was 4.299±0.8292 (median = 4.000). The Mann Whitney test, p = 0.4610 (p > 0.05) does not indicate any statistically significant difference between the medians of the given scores.

Questions 6 and 7: On a scale from 1 to 5, how comfortable do you believe the conventional and the self-ligating brackets are for the patient? (or have been told by the patient)

</table>

Regarding the final aesthetic and functional result, in the conventional system, the mean of the scores was $4.318 \pm 0.7602$ (median = 4.000) while in the self-ligating system, the mean was $4.039 \pm 0.8489$ (median = 4.000). The Mann Whitney test, $p = 0.0056$ ($p < 0.05$) indicates a statistically significant difference between the medians of the scores given to the two systems.

Questions 20 and 21: On a scale from 1 to 5, how would you rate the prices of conventional brackets, taking into consideration the quality-price ratio? What about the prices of the self-ligating system?

</table>

Concerning the quality-price ratio, in the conventional system, the mean of the scores was $4.349 \pm 0.8163$ (median = 5.000), while in the self-ligating system, it was $3.047 \pm 1.126$ (median = 3.000). The Mann Whitney test, $p < 0.0001$ ($p < 0.05$), shows us a statistically significant dif-
ference between the medians of the scores given to the two braces systems.

**DISCUSSIONS**

Our study revealed that the self-ligating system is preferred when it comes to patient comfort. Lai et al. indicated in their study that there is no evidence that pain intensity differs between conventional brackets and self-ligating brackets [7]. Yang et al. show that self-ligating brackets do not out-perform conventional brackets in relieving discomfort or improving oral health [8].

Prettyman et al. conducted a study in which the participating orthodontists reported a perceived clinical difference between self-ligating brackets and conventional brackets with regard to orthodontic treatment. Self-ligating brackets were preferred by orthodontists more often than conventional brackets for the majority of the treatment factors evaluated but their preference was influenced by certain factors [2].

Aljabaa et al. determined the orthodontists perception on the two systems and understood that orthodontics prefer the self-ligating braces for initial treatment, less chairside time, oral hygiene and less extractions and conventional braces for cost, space closure and better finishing and detailing [9].

Fleming et al. plead for insufficient quality evidence to support use of self-ligating appliances over conventional appliances [6,10]. Out of 31 comparison randomized controlled and split-mouth trials between self-ligating and conventional systems, only 9 indicated statistically significant differences, thus contradicting most of the claims of the manufacturers [11].

The American Board of Orthodontics criteria indicate that faster orthodontic treatments are better orthodontic treatments. Responses showed that patients undergoing self-ligating treatment perceive their treatment time as being shorter than expected [12]. Orthodontists, as well as their patients, are interested in reducing the global treatment time [13].

Other factors taken into consideration in the scientific literature is external apical root resorption after orthodontic treatment and extraction rate. The two do not differ between the two brackets systems [14].

**CONCLUSIONS**

The majority of the orthodontist specialists use both systems in their practice, but conventional bracket systems are more accessible taking into consideration the quality-price ratio. They consider the bonding technique more accessible in the conventional bracket system but enamel adhesion is similar in both systems.

Oral hygiene and patient comfort are superior in patients undergoing treatment with self-ligating brackets. Adjustment appointments takes less time in patients with self-ligating brackets, but there is no difference between the two systems regarding the bonding technique. Tooth movement in relation to friction is considered more effective in self-ligating braces and global treatment time is shorter with this system.

The final results from an aesthetic and functional point of view are better appraised in the conventional bracket system.
